

Advantages and disadvantages of single-mode and dual-mode fiber optic cables

Overview

Not sure which type of fiber your network needs? Fatbeam breaks down single mode vs multimode fiber and what each can offer your business in this guide.

Key Takeaways

Single-mode fiber is better for long-distance, high-bandwidth applications, while multimode fiber is more cost-effective for short-distance networks. Core

Differences Single-mode fiber (SMF) has a very narrow core, typically around 8-10 micrometers, allowing only one light mode to propagate. This minimizes signal loss and modal dispersion, enabling data transmission over long distances with high integrity and bandwidth.

Multimode fiber (MMF) has a larger core, usually 50 or 62.5 micrometers, which supports multiple light modes simultaneously. This allows multiple data streams but increases modal dispersion, limiting effective transmission distance.

Distance and Bandwidth Single-mode fiber can transmit signals over tens of kilometers without repeaters. For example, OS2 single-mode cables can carry 10 Gbps up to 40 km and even longer distances at lower speeds. Multimode fiber is suitable for shorter spans, such as local area networks (LANs), with OM3 supporting 10 Gbps up to 300 meters and OM4/OM5 slightly longer.

Single-mode fiber also offers theoretically unlimited bandwidth because only one light mode travels through the core, whereas multimode fiber's bandwidth is limited by modal dispersion, with OM5 reaching up to 28,000 MHz·km.

Cost and Installation

Multimode fiber is generally less expensive to produce and install because it can use lower-cost light sources like LEDs or VCSELs. Single-mode fiber requires precise laser sources and more careful installation due to its narrow core, making it more costly. However, for long-distance or high-speed backbone networks, the performance benefits of single-mode fiber outweigh the higher cost.

Use Cases Single-mode fiber: Ideal for long-haul telecommunications, wide area networks (WANs), and high-speed backbone connections where distance and signal integrity are critical. Multimode fiber: Best for short-distance applications such as data centers, office networks, and campus LANs where cost efficiency and ease of installation are priorities.

Conclusion

Choosing between single-mode and multimode fiber depends on your network requirements. Single-mode fiber is superior for long-distance, high-bandwidth, and high-performance applications, while multimode fiber is more economical and suitable for shorter distances. For most enterprise LANs, multimode is sufficient, but for backbone or intercity links, single-mode is the better choice.
