Connecting pigtails and jumpers

Overview

Fiber Jumpers vs. Pigtails: What's the Difference?

How Do They This guide breaks down the key differences between fiber jumpers and pigtails, their applica.

Key Takeaways

Fiber optic pigtails are fusion-spliced to cable fibers inside a terminal box, and jumpers (patch cords) connect the pigtails to equipment for flexible, low-loss optical connections.

Understanding Pigtails and Jumpers

Pigtails are short fiber optic cables with a factory-polished connector on one end and a bare fiber on the other. The bare end is fusion-spliced to the fiber core of a main cable inside a fiber terminal box or optical distribution frame (ODF) to create a permanent, low-loss connection. Pigtails are used to establish the back-end interface of a fiber network and are available in single-mode or multi-mode, with various connector types such as FC, SC, LC, and ST.

Jumpers, also called patch cords, are fiber optic cables with connectors on both ends. They are used to connect pigtails to network equipment, such as optical transceivers, switches, or routers, allowing for flexible and reconfigurable connections. Jumpers are not meant for permanent splicing but for front-end patching, enabling quick moves, adds, or changes without disturbing the spliced fibers.

How to Connect Pigtails and Jumpers

Splice the Pigtail: Insert the bare end of the pigtail into a fiber terminal box and fusion-splice it to the corresponding fiber core of the main cable. This creates a permanent optical path from the cable to the connectorized end of the pigtail. Patch with a Jumper: Connect the connectorized end of the pigtail to the connector on the jumper.

The other end of the jumper is plugged into the optical transceiver or network device, completing the optical link. Verify Connection: Use an optical power meter or OTDR to ensure minimal loss and proper signal transmission.

Key Points

Pigtails provide permanent, low-loss splicing; jumpers provide flexible, reconfigurable connections. Connector types must match between pigtails and jumpers (e.g., LC-to-LC, SC-to-SC) to ensure proper coupling. Terminal boxes or ODFs protect splices and organize multiple fibers, allowing multiple pigtails to lead out to jumpers for equipment connections.

By following this workflow, fiber networks maintain high performance, low loss, and easy maintenance, while allowing technicians to quickly reconfigure connections without disturbing the spliced fibers.
