

How to check the optical port speed of a switch

Overview

By reading internal parameters of optical transceivers on switches, users can monitor link status, real-time transmit/receive power, operating temperature and other data.

Key Takeaways

You can check the optical port speed on a switch using CLI commands like show interface status or show interface transceiver detail to view the negotiated speed, duplex, and module type.

Using CL

I Commands on Cisco Switches
Check Interface Status
Run show interface status to see all ports, their link state, speed, and type. Optical ports will typically show as SFP or fiber with the current speed (e.g., 1G, 10G, 25G) and whether the link is up.
Example output: CodeCopyGi1/0/1 connected 1000 full SFP-1GBase-SX
View Detailed Transceiver Information
Use show interface transceiver detail or show interface transceiver properties to get Digital Diagnostic Monitoring (DDM) metrics such as Tx/Rx power, temperature, voltage, and the exact speed supported by the SFP module.

This command also confirms the module type and vendor, helping detect compatibility issues. Check Inventory
show inventory lists all installed SFPs with Product ID (PID), Version ID (VID), and serial number. This helps verify that the optical module supports the desired speed.

Check Interface Capabilities `show interface capabilities` displays the speeds and duplex modes the port can negotiate. If the port is set to auto, the actual speed depends on the connected device. Optional: From a Connected PC On Windows, open Command Prompt and run `wmic nic get name, speed` to see the speed of the network adapter connected to the switch port.

On Mac, use Terminal commands like `ifconfig` to check the link speed of the connected interface.

Notes

If the port shows auto speed, the actual speed is negotiated with the connected device. Forcing a specific speed can be done in interface configuration mode:
`CodeCopyconf t interface speed 1000duplex full` Always ensure the SFP module is compatible with the switch and supports the intended speed to avoid link errors. By following these steps, you can accurately determine the operational speed of optical ports, verify link health, and troubleshoot connectivity issues.
