

Round and square heads of beam splitters

Overview

While most beam splitters have only two output ports, there are also beam splitters with multiple outputs. They may be realized, for example, based on diffractive optics.

Key Takeaways

Beam splitters come in round (circular) and square (cube) forms, with the choice affecting mounting, alignment, and optical performance. Square (Cube) Beam Splitters Square or cube beam splitters are typically made from two triangular prisms glued together, forming a cube shape. They are available in polarizing and non-polarizing models and are often premounted for easy integration into optical systems.

Cube beam splitters provide: Stable alignment due to their rigid cube structure. Compatibility with lens tube and cage systems. High surface flatness and quality, allowing precise splitting ratios and minimal wavefront distortion.

High damage threshold coatings, suitable for laser applications. Cube beam splitters are ideal for setups requiring precise beam manipulation, such as interferometry, laser experiments, and photonics instrumentation. Round (Circular) Beam Splitters Round beam splitters, often referred to as plate or circular beam splitters, are typically flat optical plates with a coated front surface and an anti-reflection (AR) coated back surface.

They are designed to: Minimize ghosting and interference through wedged or AR-coated surfaces. Fit into circular mounts, making them convenient for rotational or compact optical setups. Provide flexibility in applications where space is limited or where the beam splitter needs to be rotated or adjusted.

Round beam splitters are commonly used in fluorescence microscopy, illumination systems, and general optical experiments where precise cube mounting is not required. Key Differences

Feature	Square (Cube)	Round
Shape	Cube	Circular
Mounting	Premounted, compatible with cage/lens tube systems	Fits circular mounts, can rotate
Alignment	Stable, fixed	Flexible, may require careful alignment
Optical Performance	High flatness, precise splitting ratio	Can minimize ghosting with AR coatings, slightly more wavefront error possible
Applications	Laser systems, interferometry, photonics	Microscopy, illumination, general optics

Summary The choice between round and square beam splitters depends on the mechanical mounting requirements, optical precision, and application type.

Cube splitters offer rigid alignment and high precision, while round splitters provide flexibility and ease of integration into circular mounts or compact setups.

Beam Splitter Selection Guide

These beamsplitters are made from high grade glass materials with laser grade surface flatness and surface quality and have a tighter tolerance on the splitting ratio.

Beam splitter

Overview Designs Phase shift Classical lossless beam splitter Use in experiments Quantum mechanical description Reflection beam splitters

In its most common form, a cube, a beam splitter is made from two triangular glass prisms which are glued together at their base using polyester, epoxy, or urethane-based adhesives. (Before these synthetic resins, natural ones were used, e.g. Canada balsam.) The thickness of the resin layer is adjusted such that (for a certain wavelength) half of the light incident through one "port" (i.e., face of the cube) is reflected and th

Thorlabs · Optical Beamsplitters

Thorlabs offers a wide range of optical beamsplitters. Our plate beamsplitters have a coated front surface that determines the beam splitting ratio while the back

Beam splitter plates

The beam splitter plates manufactured by Fleige Optik consist of optical glass, with one surface carrying the splitter layer. An anti-reflection coating is usually applied to the reverse side to avoid disturbing

Beamsplitters Product Overview

RMS or rms means "Root Mean Square". In a simple form (only "positive" deviations, as in a "salad bowl"), the RMS value is approximately 70% of the

Diffraction Optical Elements (DOEs) | Beam Splitter & Shaper

A Top Hat Beam Shaper is a form of DOE that transforms a Gaussian (TEM₀₀) input laser beam into a uniform intensity spot of the desired shape. This output point can be round, square, rectangular as
