The optical module s output power becomes zero

Overview

One of the most common reasons for decreased laser output is the degradation of optical components. Mirrors, lenses, and other components within the laser system can accumulate dust, dirt, or other contaminants, leading to scattering or absorption of the laser light. Understanding the sources of optical losses is crucial in diagnosing and rectifying these power reductions to maintain optimal laser performance. Transmitter power characterizes the average optical power output from the laser under rated conditions, while receiver sensitivity indicates the minimum. Customers in the use of optical modules will more or less encounter a variety of failure problems, such as optical module model selection is correct, the use of jumper is correct and some common problems, customers have the ability to judge and have a clear solution, but for some of the use of. Average optical power refers to the optical power outputted by the optical module's transmitter under normal working conditions, which can be understood as the intensity of light.
