

UPS primarily provides backup power for the system

Overview

The three general categories of modern UPS systems are on-line, line-interactive and standby: • An online UPS uses a "double conversion" method of accepting AC input, to DC for passing through the (or battery strings), then inverting back to 120 V/230 V AC for powering the protected equipment.

Key Takeaways

A UPS provides immediate backup power, voltage regulation, and surge protection to keep devices running during power outages or fluctuations.

Core Functionality

A UP

S (Uninterruptible Power Supply) is an electrical device designed to provide emergency power to connected equipment when the main power source fails. It acts as a bridge between a power outage and the activation of longer-term backup systems, such as generators, ensuring that devices remain operational without interruption.

The UP

S draws energy from internal batteries, supercapacitors, or flywheels to supply power almost instantaneously when the input power is lost.

Key Benefits

Power Continuity: The UPS ensures that critical systems like computers, servers, medical devices, and networking equipment continue running during outages, preventing data loss and operational disruption. **Voltage Regulation:** Many UPS systems include automatic voltage regulation (AVR) to smooth out under-voltages and over-voltages, maintaining a stable power supply without draining the battery. **Surge and Spike Protection:** UPS units protect devices from sudden voltage spikes caused by lightning, grid switching, or other disturbances, reducing the risk of hardware damage.

Intelligent Communication: Advanced UPS models can communicate with connected devices to initiate safe shutdown procedures before battery depletion, preserving data integrity.

Types of UPS Systems

Online UP

S: Provides continuous power from the battery through double conversion, ideal for sensitive equipment.

Line-

Interactive UP

S: Maintains the inverter in line and switches to battery when power fails, offering voltage correction. Standby (Offline) UPS: Supplies power directly from the mains and switches to battery only during outages, often used with generators.

Runtime and Sizing

Most UP

S systems provide short-term power, typically 5 to 15 minutes, which is sufficient to either safely shut down equipment or start a generator.

UP

S units are rated in volt-amperes (VA), which indicates the maximum load they can support. Choosing the right UPS depends on the total power consumption of connected devices and the desired runtime.

Summary

A UP

S is more than just a battery backup; it ensures uninterrupted operation, stabilizes voltage, protects against surges, and allows safe shutdown of critical systems. It is essential for environments where even brief power interruptions can cause data loss, equipment damage, or operational downtime.
